## Supplementary material

Table S1. Butterfly species recorded in the study, with their corresponding classification into the different categories of resource specialization and dispersal ability. Trophic specialization of the larvae: 1, monophagous; 2, oligophagous; 3, polyphagous. Habitat specialization (1 to 4, from most specialized to least specialized) measured by the ‘species specialization index’ (SSI) of Julliard et al. (2006), whenever a species occurred in at least three monitoring transects. Dispersal ability (1 to 4, from minimal to maximal) according to various references and unpublished information from the study area (see text for details).

Table S2. Factor loadings of land-cover variables (measured in a buffer area of 5 km around each butterfly site) on the first axis of the principal component analysis summarising landscape structure.

Landscape PCA1 Analysis	
Eigenvalue	1.88
Percentage	31.36
Landcover variable	Factor loadings
Open forest	0.44
Dense forest	0.39
Farmland	-0.55
Urban cover	-0.39
Bare ground	0.29
Shrubland	0.33

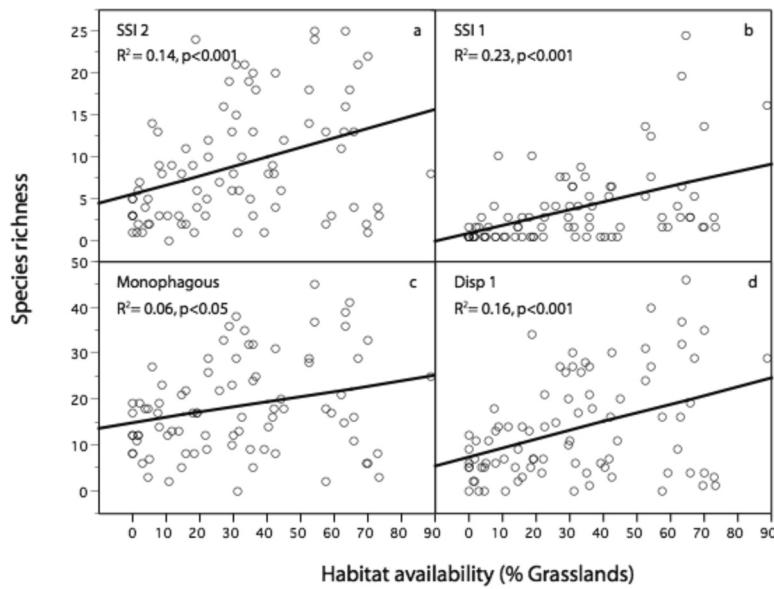

Figure S1. Observed trends between species richness and percentage of grassland habitat for specialist groups measured at the local scale (i.e. the proportion of grassland within the 5-m wide census area along the transects). (a) SSI 2 habitat specialists, (b) SSI 1 habitat specialists, (c) Monophagous species, and (d) Dispersal class 1.

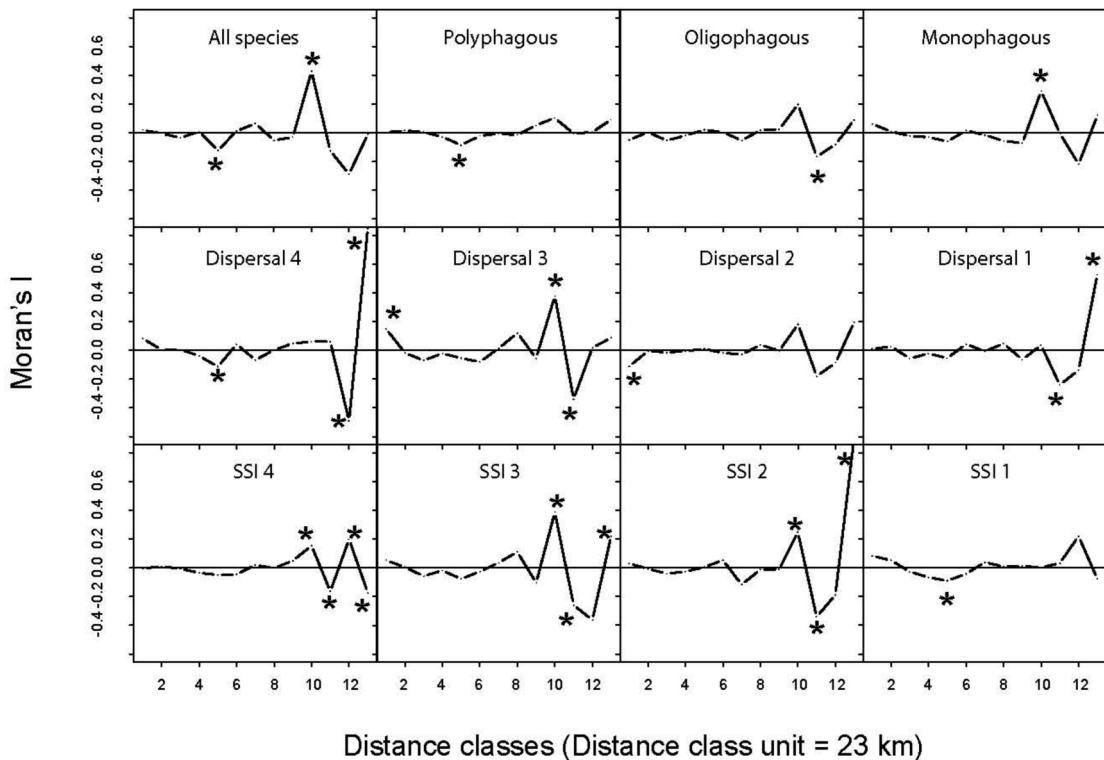

Figure S2. Moran's I correlograms of the residuals of the models with minimum AIC<sub>c</sub> values in Table 1 (bold values). Significant auto-correlation at each distance class is indicated by an asterisk. The number of distance classes applied in the correlograms was calculated following Sturge's rule.

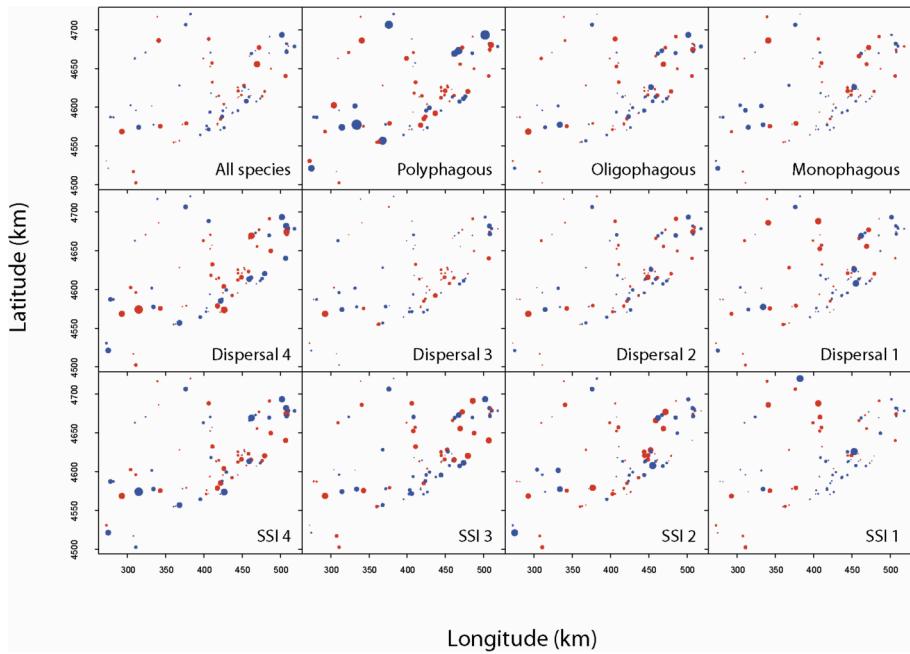

Figure S3. Spatial maps of the residuals of the models. Positive and negative residuals were extracted from models with minimum AIC<sub>c</sub> values in Table 1 (bold values), and are represented by blue and red dots respectively. The size of the dot is proportional to the numeric value of the residual. The presence of spatial autocorrelation in the residuals of the model produces a more clustered distribution.
